

ABSTRACT

Composition and methods are described for low immunogenic protein formulations. An example of such a protein is antihemophilic factor (FVIII). The
5 composition generally includes the protein, polypeptide or peptide, one or more agents that bind to epitope domains of the proteins to form a complex. Buffers containing salts may be used to stabilize this interaction. For example, Factor VIII and serine containing phospholipids in buffer salts containing Ca^{2+} and Na^{+} can be used to prepare protein-lipid structures. These complexes are useful for treatment of
10 diseases such as Hemophilia. A method for the formation of novel non-liposomal structures is also disclosed.
